

Prompt: Interactive “Google Earth” Style AI Continents Website

Copy the following prompt into Claude AI. The goal is to have Claude build a simple, locally runnable interactive website without unnecessary infrastructure.

Goal

Create a locally runnable, interactive Earth/globe-style website inspired by Google Earth. The main screen should show a realistic-looking 3D or stylized globe with light-green interactive buttons/markers positioned over each continent. Clicking a continent opens a small information pop-up.

1. Main Globe

Display a large Earth/globe in the center of the page. Use a dark space background with stars. Continents should be clearly visible. Allow the user to rotate and zoom the globe if practical. Keep the Earth as the main focus and use a clean, modern design rather than copying Google's branding exactly.

2. Continent Interaction Buttons

Place a light-green circular button/marker over each continent: North America, South America, Europe, Africa, Asia, Australia/Oceania, and Antarctica. Markers should use recognizable geographic positions, be clearly visible, have a subtle glow/hover effect, and be clickable.

3. Pop-Up Windows

When a continent is clicked, display a small floating pop-up card near the relevant location. The card should have the continent name as its title and a short paragraph about how AI can benefit and negatively affect that continent. Use a dark/slightly transparent background, white text, a light-green accent, a close button, and a subtle fade/scale animation. Keep the card small enough that it does not cover most of the globe.

4. AI Information

Use these balanced descriptions:

North America — AI is widely used in technology, healthcare, finance, transportation and entertainment. It can increase productivity, improve medical research and create new industries, but can also contribute to job disruption, privacy concerns, misinformation and increased computing-energy demand.

South America — AI could help improve agriculture, climate monitoring, healthcare access and education, especially where services are difficult to reach. Unequal access to technology, limited infrastructure and differences in digital skills could mean some communities benefit less.

Europe — AI is being used in manufacturing, healthcare, scientific research and public services. It can improve efficiency and innovation, while raising concerns about employment changes, privacy, misinformation and the difficulty of regulating rapidly developing technologies across many countries.

Africa — AI has potential applications in healthcare, agriculture, education, financial services and climate monitoring. It could expand services to underserved populations, but limited internet access, computing infrastructure, investment and digital skills can make adoption harder and potentially increase existing inequalities.

Asia — Asia contains some of the world's largest AI research, technology and manufacturing industries. AI is used in robotics, manufacturing, medicine, transportation and education, creating economic opportunities while also raising concerns about employment disruption, surveillance, data privacy and unequal access.

Australia/Oceania — AI can support healthcare, agriculture, mining, environmental monitoring and scientific research, while Pacific nations could use AI for climate and disaster planning. Challenges include geographic isolation, infrastructure costs and unequal access to advanced technology.

Antarctica — AI can assist Antarctic research by analyzing satellite imagery, monitoring ice sheets, studying wildlife and helping scientists understand climate change. Benefits are mainly scientific and environmental, while

challenges include expensive equipment, limited connectivity and the energy required for computing and research.

5. Visual Style

Use a dark navy/black space background, a blue-and-green Earth, light-green interaction markers similar to #90EE90, white/light-gray typography, subtle shadows and glows, smooth transitions and rounded pop-up cards. The interface should feel like an interactive educational exploration tool rather than a conventional website.

6. Local Operation

The project must run entirely locally. Do not use a database, login system, backend, external API, or port configuration. Keep it primarily client-side and avoid unnecessary HTML complexity. If a JavaScript globe/3D library is used, make it easy to include locally or provide a simple fallback when external dependencies are unavailable.

7. Basic Interaction Flow

Open website → Interactive Earth appears → User rotates/zooms Earth → User sees light-green continent markers → User clicks a marker → Small continent pop-up appears → User reads AI benefits and challenges → User closes pop-up → User selects another continent.

8. Implementation Detail

Make the continent information data-driven rather than creating a separate interface for every continent. Store each continent's name, geographic marker position and description in a JavaScript data structure. Use one reusable pop-up component that displays the selected continent's information.

Overall Objective

Make the experience feel like the user is exploring Earth and discovering how AI affects different parts of the world, with the globe remaining the central interactive element throughout. Keep the code understandable, lightweight and easy to run locally.
